Cloning, expression and characterization of YSA1H, a human adenosine 5’-diphosphosugar pyrophosphatase possessing a MutT motif

Lakhdar GASMI, Jared L. CARTWRIGHT and Alexander G. McLENNAN

School of Biological Sciences, Life Sciences Building, University of Liverpool, P.O. Box 147, Liverpool L69 7ZB, U.K.

The human homologue of the Saccharomyces cerevisiae YSA1 protein, YSA1H, has been expressed as a thioredoxin fusion protein in Escherichia coli. It is an ADP-sugar pyrophosphatase with similar activities towards ADP-ribose and ADP-mannose. Its activities with ADP-glucose and diadenosine diphosphate were 56% and 20% of that with ADP-ribose respectively, whereas its activity towards other nucleoside 5’-diphosphosugars was typically 2–10%. cADP-ribose was not a substrate. The products of ADP-ribose hydrolysis were AMP and ribose 5-phosphate. \[ K_m \] and \[ k_{cat} \] values with ADP-ribose were 60 \( \mu \)M and 5.5 s\(^{-1}\) respectively. The optimal activity was at alkaline pH (7.4–9.0) with 2.5–5 mM Mg\(^{2+}\) or 100–250 \( \mu \)M Mn\(^{2+}\) ions; fluoride was inhibitory, with an \( IC_{50} \) of 20 \( \mu \)M. The YSA1H gene, which maps to 10p13–p14, is widely expressed in all human tissues examined, giving a 1.4 kb transcript. The 41.6 kDa fusion protein behaved as an 85 kDa dimer on gel filtration. After cleavage with enterokinase, the 24.4 kDa native protein fragment ran on SDS/PAGE with an apparent molecular mass of 33 kDa. Immunoblot analysis with a polyclonal antibody raised against the recombinant YSA1H revealed the presence of a protein of apparent molecular mass 33 kDa in various human cells, including erythrocytes. The sequence of YSA1H contains a MutT sequence signature motif. A major proposed function of the MutT motif proteins is to eliminate toxic nucleotide metabolites from the cell. Hence the function of YSA1H might be to remove free ADP-ribose arising from NAD\(^{+}\) and protein-bound poly- and mono-(ADP-ribose) turnover to prevent the occurrence of non-enzymic protein glycation.

Key words: ADP-ribose, nucleotide sugar, nudix hydrolase, protein glycation.

INTRODUCTION

The MutT sequence motif proteins are a recently described family of mostly small, soluble nucleotide pyrophosphatases named after the 16 kDa Escherichia coli mutT gene product, a hydrolase with a strong preference for the mutagenic nucleotide 8-oxo-dGTP [1]. They all possess the sequence signature motif \[ GX_4EX_4[UAX]RE[UT]XEEXGU \] (single-letter codes, where U is a hydrophobic amino acid, and the square brackets indicate that the position could be occupied by any of the amino acids within the brackets) [2]. The \( E. coli \) genome sequence reveals 11 further proteins with perfect or closely related MutT motifs, several of which have now been cloned and characterized [3]. The substrate specificities of these other proteins varies from quite specific to relatively broad; known substrates include dATP, NADH, nucleoside 5’-diphosphosugars (NDP-sugars) and dinucleoside polyphosphates. Because all these substrates have the general structure of a nucleoside diphosphate linked to another moiety, \( X \), the name ‘nudix’ hydrolase has been proposed for this family. The function of members of this protein family might be to cleanse the cell of potentially deleterious endogenous nucleotide metabolites and to modulate the accumulation of metabolic intermediates by diverting them into alternative pathways in response to biochemical need [3].

MutT motif proteins are also found in eukaryotes, including humans [4]. Known human proteins include the MutT orthologue MTH1 [5], diadenosine 5’,5”-P\(_1\)-P\(_2\)-tetraphosphatase (Ap\(_P\), ADP-ribose diphosphatase) [6] and diphosphoinositol polyphosphate phosphohydrolase (DIPP) [7]. DIPP is homologous with the recently described Ap\(_P\), A hydrolases from budding and fission yeasts and, like them, is remarkable in its ability to hydrolyse the non-nucleotide diphosphoinositol polyphosphates in addition to the structurally unrelated diadenosine polyphosphates [8]. A survey of the GenBank expressed sequence tag (EST) database suggests the existence of at least six further human MutT motif proteins, including a protein encoded in an anti-sense transcript of the basic fibroblast growth factor gene [9], a protein closely related to DIPP (DIPP2) [7], and a homologue of the Saccharomyces cerevisiae YSA1 protein. YSA1 has been reported to have ADP-ribose pyrophosphatase activity (EC 3.6.1.13), although no details of this activity have been published [3,10].

ADP-ribose is the most significant ADP-sugar in mammalian cells. It is generated by the turnover of NAD\(^{+}\) and protein-bound poly- and mono-(ADP-ribose) and, if allowed to accumulate, could be hazardous to the cell by virtue of its ability to modify protein histidine, lysine and cysteine residues by non-enzymic glycation [11–13] and to bind to ATP-activated K\(^{+}\) channels [14]. The elimination of free ADP-ribose therefore seems to fall within the category of ‘housecleaning’ functions proposed for the MutT motif family. An ADP-ribose pyrophosphatase has recently been isolated from human erythrocytes [12,15], whereas three cytoplasmic and one mitochondrial ADP-ribose pyrophosphatases in rat liver have been described [16]. A possibly distinct ADP-sugar pyrophosphatase (EC 3.6.1.21) has also been isolated from...
mammalian liver [17]. However, the amino acid sequences of none of these enzymes have been determined. Here we report the cloning, expression and characterization of YSA1H, the human homologue of the yeast YSA1 protein, and show that it is an ADP-sugar pyrophosphatase with its highest activity towards ADP-ribose, ADP-mannose and ADP-glucose.

Since this paper was submitted the Human Genome Nomenclature Committee (HGNC) has approved gene symbols for the human MutT motif proteins. Accordingly the YSA1H gene is designated NUDT5. Full details can be found on http://www.gene.ucl.ac.uk/users/hestер/npym.html or by contacting the committee (e-mail name@galton.ucl.ac.uk).

**EXPERIMENTAL**

**Materials**

Mononucleotides, dinucleoide polyphosphates, NDP-sugars and nucleoside 5'-diphosphoalcohols were from Sigma. [32P]UTP (800 Ci/mmol) was from ICN; NAD+, NADH, NADP+, NADPH, calf intestinal alkaline phosphatase, yeast inorganic pyrophosphatase, EcoRI and NcoI were from Boehringer Mannheim; pET 32b (+) was from Novagen; Pfu DNA polymerase was from Stratagene; I. M. A. G.E. clone 310860 was obtained from the UK Human Genome Mapping Project Resource Centre.

**Cloning of YSA1H cDNA**

I.M.A.G.E. clone 310860 contains an insert corresponding to a YSA1H cDNA in the polylinker-modified plasmid pT7T3D. The sequence of the insert was confirmed (see Figure 1) and the insert was then amplified by PCR. The 29-mer oligonucleotide forward sequence of the insert was confirmed (see Figure 1) and the insert YSA1H cDNA in the polylinker-modified plasmid pT7T3D. The I.M.A.G.E. clone 310860 contains an insert corresponding to a homologue of the yeast YSA1 protein, and show that it is an ADP-sugar pyrophosphatase with its highest activity towards inorganic pyrophosphatase [16, 18]. The standard assay (200 μl) for phosphodiester substrates was incubation for 10 min at 37°C with 50 mM Tris/HCl (pH 7.5)/5 mM MgCl2/1 mM dithiothreitol/0.3 mM substrate/0.25 μg of Trx–YSA1H fusion protein and 0.5 μg (1 unit) of alkaline phosphatase. Phosphomonoester substrates were assayed as above, except that 0.5 μg (100 m-units) of inorganic pyrophosphatase was used instead of alkaline phosphatase. The P$_i$ released in each case was measured colorimetrically. P$_i$ released from NADP$^+$ and NADPH in control assays without YSA1H was subtracted. Kinetic parameters for ADP-ribose hydrolysis were determined by measuring the P$_i$ released in the alkaline-phosphatase-coupled assay as described. Non-specific alkaline phosphodiesterase (nucleotide pyrophosphatase) activity was assayed with thymidine 5'-monophospho-p-nitrophenyl ester as substrate [19].

Reaction products generated from the different substances were identified by high-performance anion-exchange chromatography. Reaction mixtures containing 50 mM Tris/HCl, pH 7.5, 5 mM MgCl$_2$, 1 mM dithiothreitol, 0.3 mM substrate and 3 μg of Trx–YSA1H fusion protein were incubated at 37°C for 30 min in a volume of 200 μl. Samples (100 μl) of the reaction mix were applied to a 1 ml Resource-Q column (Pharmacia) equilibrated with 45 mM ammonium acetate (pH adjusted to 4.6 with H$_3$PO$_4$) and eluted with a linear gradient from 0% to 100% (v/v) 0.5 M Na$_2$HPO$_4$ (adjusted to pH 2.7 with acetic acid) for 10 min at a flow rate of 1 ml/min [15]. Elution was monitored at 260 nm and peaks were identified with the aid of standards.

**Northern and dot-blot analyses**

A 32P-labelled anti-sense RNA to the YSA1H cDNA was generated from I.M.A.G.E. clone 310860 by using an in vitro transcription kit (Ambion). [32P]UTP and T3 RNA polymerase in accordance with the manufacturer’s instructions. A Multiple Choice$	extsuperscript{™}$ Northern blot (OriGene) containing poly(A)$^+$-selected RNA from various human tissues (2 μg per lane) was probed overnight with the RNA probe (10$^4$ c.p.m./ml) at 64°C. The blot was washed twice for 15 min each with SSC (0.15 M NaCl/0.015 M sodium citrate) containing 0.5% SDS at 64°C. The bound 32P-labelled probe was detected with a PhosphorImager (Bio-Rad). The blot was then stripped for re-use by using the Strip-EZ solutions provided with the transcription kit. A Human RNA Master Biot$	extsuperscript{™}$ dot-blot (Clontech) containing normalized loadings of poly(A)$^+$ RNA from 50 different human tissues was processed as above, except that the ExpressHyb$	extsuperscript{™}$ hybridization buffer provided with the blot was used.

**Immunoblotting**

The Trx and His tags were cleaved from the fusion protein with thrombin and the resulting YSA1H protein with a residual N-terminal S-tag was used to raise a rabbit polyclonal antiserum by standard procedures. Cell lysates were separated by SDS/PAGE [13% (w/v) gel]. The gels were then equilibrated immediately in transfer buffer [10 mM Caps/NaOH (pH 11.0)/10% (v/v)
methanol] for at least 10 min before electrophoretic transfer of the separated proteins to a nitrocellulose membrane at 150 mA and 4 °C for 2 h. The membrane was blocked overnight at 4 °C with 3% (w/v) fat-free powdered milk and 0.2% (v/v) Tween 20 in PBS and then probed with a 1:1000 dilution of whole anti-YSA1H antiserum followed by a 1:5000 dilution of horseradish peroxidase-conjugated goat anti-rabbit IgG (Bio-Rad). After being washed, the membrane was developed with the peroxidase substrate diaminobenzidine tetrahydrochloride (Sigma).

**Other methods**

Protein concentrations were estimated by the Coomassie Blue binding method [20]. N-terminal sequencing and electrospray mass spectrometric analysis were performed as described previously [6,18].

**RESULTS**

**Cloning, expression and purification of YSA1H**

A BLAST 2.0 search of the GenBank EST database with the *S. cerevisiae* YSA1 sequence yielded a large number of overlapping homologous human clones that, when assembled, revealed a 973-base sequence with a 657-base open reading frame (ORF) potentially encoding a 219-residue, 24.3 kDa protein, including the N-terminal methionine residue (Figure 1). This ORF had 63% amino acid sequence identity with the 26.1 kDa YSA1 protein over a 69-residue region encompassing the MutT motif (see Figure 6). We have named this putative human YSA1 homologue, or YSA1H. That the predicted sequence represents the full-length protein is indicated by the presence of multiple stop codons both upstream and downstream of the ORF and by the highly favourable sequence context of the proposed initiator codon, AAAATGG (Figure 1) [21]. Human sequence-tagged sites corresponding to these ESTs have been mapped to chromosome 10p13–p14 between the markers D10S189 and D10S191 by the International Radiation Hybrid Mapping Consortium [22]. The UniGene entry number is Hs.11817.

A YSA1H cDNA was amplified by PCR from I.M.A.G.E. clone 310860, which was predicted to contain the full-length cDNA. For expression, the PCR fragment was inserted into the pET32b(+) vector and the recombinant plasmid (pET-YSA1H) was then used to transform *E. coli* BL-21(DE3) cells to generate a His-tagged thioredoxin fusion protein of predicted mass 41.6 kDa. After induction with IPTG, cell samples were analysed by SDS-PAGE, which showed that the soluble fraction contained a major IPTG-inducible protein band migrating with an apparent molecular mass of 47 kDa, which was therefore presumed to be the desired product (Figure 2a). The expressed Trx–YSA1H fusion protein was then purified in a single step to apparent homogeneity on a Ni²⁺/NTA-agarose column (Figure 2b).

**Substrate specificity**

All MutT motif proteins studied so far have nucleotide pyrophosphatase activity that hydrolyses compounds containing an NDP-linked to another moiety. Therefore a range of nucleotides was assayed to determine the substrate specificity of Trx–YSA1H. For expression, the PCR fragment was inserted into the pET32b(+) vector and the recombinant plasmid (pET-YSA1H) was then used to transform *E. coli* BL-21(DE3) cells to generate a His-tagged thioredoxin fusion protein of predicted mass 41.6 kDa. After induction with IPTG, cell samples were analysed by SDS-PAGE, which showed that the soluble fraction contained a major IPTG-inducible protein band migrating with an apparent molecular mass of 47 kDa, which was therefore presumed to be the desired product (Figure 2a). The expressed Trx–YSA1H fusion protein was then purified in a single step to apparent homogeneity on a Ni²⁺/NTA-agarose column (Figure 2b).

**Figure 2** Overexpression and purification of Trx–YSA1H fusion protein

(a) *E. coli* BL-21(DE3) cells transformed with pET-YSA1H were induced with 1 mM IPTG for up to 4 h. Aliquots were taken at hourly intervals, boiled in sample buffer, analysed by SDS/PAGE and stained with Coomassie Blue. (b) YSA1H protein after purification on Ni²⁺/NTA-agarose as described in the Experimental section. The protein standards were myosin (205 kDa), β-galactosidase (116 kDa), phosphorylase b (97 kDa), BSA (66 kDa), ovalbumin (45 kDa) and carbonic anhydrase (29 kDa).

**Figure 1** Nucleotide sequence of the YSA1H cDNA and predicted amino acid sequence of the YSA1H protein

In-frame stop codons upstream and downstream of the YSA1H ORF are indicated with three asterisks. The presumed initiating ATG in its strong initiating context AAAATGG is underlined with dashes. The MutT motif is underlined; the invariant amino acids are shown in bold. The likely polyadenylation signal AATAAAA is doubly underlined.
Table 1  Substrate specificities of YSA1H, human erythrocyte ADP-ribose pyrophosphatase, rat liver ADP-ribose II and calf liver ADP-sugar hydrolase

Results are expressed as the percentage activity obtained with ADP-ribose under the assay conditions used. Values in columns three to six are published (references in square brackets) and are based on different assay conditions from those used for YSA1H. Values for YSA1H are derived from assays containing 5 mM Mg\(^{2+}\) ions and are the averages of triplicate determinations. Abbreviation: n.t., not tested.

20-fold. No activity was observed with thymidine-5’-monophospho-p-nitrophenyl ester as substrate; therefore YSA1H is devoid of alkaline phosphodiesterase 1 activity (EC 3.1.4.1). Comparative data are also presented in Table 1 for the human erythrocyte ADP-ribose pyrophosphatase, rat liver ADP-ribose II and calf liver ADP-sugar hydrolase. When assayed with 5 mM Mn\(^{2+}\) in place of Mg\(^{2+}\), rat liver ADP-ribose II shows greatly increased activity with UDP-sugars and CDP-sugars and CDP-alcohols [16]. YSA1H activity towards CDP-glycerol was increased 4-fold when Mn\(^{2+}\) replaced Mg\(^{2+}\), in comparison with the 50-fold increase observed with ADP-ribose II, whereas the activity of YSA1H towards ADP-sugars was decreased by 50–70% with Mn\(^{2+}\). The UV-absorbing nucleotide reaction products generated from NDP-sugars were identified by HPLC and in each case were the corresponding NMP (Figure 3). The other product was assumed to be the sugar 5-phosphate.

Kinetic parameters and reaction requirements

Kinetic parameters were determined with ADP-ribose as substrate. \(K_m\) and \(V_{\text{max}}\) values were 60 \(\mu\)M and 8 \(\mu\)mol/min per mg respectively. The latter figure corresponds to a \(k_{\text{cat}}\) of 5.5 s\(^{-1}\). With ADP-ribose as substrate, the enzyme displayed optimal activity at alkaline pH (7.4–9.0) with 2.5–5 mM Mg\(^{2+}\) or 100–250 \(\mu\)M Mn\(^{2+}\) ions (results not shown). In common with other MutT motif proteins, fluoride was inhibitory, with an IC\(_{50}\) of approx. 20 \(\mu\)M.

Tissue specificity of YSA1H mRNA expression

Northern blot and dot-blot analyses were performed to determine respectively the size and tissue distribution of YSA1H mRNA transcripts. A transcript of approx. 1.4 kb was detected in all human tissues present on the Northern blot (Figure 4a). A larger but less prominent transcript of approx. 5 kb was also detected, which might represent residual pre-mRNA as well as a smaller 1.1 kb species that was most prominent in placenta. Expression seemed stronger in lung, small intestine and stomach than in muscle, testis or placenta, but the blot was not normalized for differential rates of expression. A better comparison of tissue expression was obtained by dot-blot analysis with a blot that had been normalized with respect to eight different housekeeping genes. This showed that YSA1H was expressed in all 50 different human tissues present on the blot (Figure 4b). Although the amount of mRNA does not necessarily reflect expression at the protein level, such widespread expression is consistent with a role as a housecleaning enzyme required in all tissues. The level of mRNA expression was, however, higher in liver, kidney, pituitary, placenta and thymus than in other adult tissues and lowest in bone marrow, lymph nodes and certain areas of the brain.

Size and presence of YSA1H protein in human cell extracts

On gel-filtration analysis, the 41.6 kDa Trx–YSA1H fusion protein had a molecular mass of 85 kDa, suggesting that it
Human ADP-sugar pyrophosphatase

Figure 3 Identification of AMP reaction product from hydrolysis of ADP-ribose

Assays containing 0.3 mM ADP-ribose were incubated with or without 3 µg of Trx–YSA1H fusion protein for 30 min, then applied to a 1 ml Resource-Q anion-exchange column as described in the Experimental section. The positions of standards are indicated. The lines are as follows: solid line, without enzyme; short broken line, with enzyme; long broken line, gradient.

behaved as a dimer in solution (Figure 5). To show that the YSA1H protein was actually expressed in human cells, a rabbit polyclonal antibody was raised against recombinant YSA1H from which most of the vector fusion sequences had been removed by treatment with thrombin. Figure 6(a) shows an immunoblot analysis of the complete Trx–YSA1H fusion protein (lane 1) and after cleavage with thrombin, which yielded a product of theoretical molecular mass 27.5 kDa (lane 2), and enterokinase, which produced a near-native protein with a single alanine residue N-terminal to the initiating methionine residue (lane 3). Although the predicted molecular mass of the recombinant alanyl-YSA1H was 24.4 kDa, it ran on SDS-PAGE with

Figure 7 Multiple sequence alignment of YSA1H and related sequences

A 69-residue section of the YSA1H sequence encompassing the MutT motif was aligned by using the CLUSTAL W program with sequences from rat (AA858886), mouse (AI508860), Saccharomyces cerevisiae YSA1 (Q01976), Caenorhabditis elegans (AF067946), Treponema pallidum (O83713), Bacillus subtilis YQKG (P54570) and Synechocystis sp. (P72646), and the Escherichia coli orf186 (P45799), Methanococcus jannaschii ADP-ribose pyrophosphatase (Q58549) and E. coli orf209 (P36651) sequences; the numbers in parentheses are the accession numbers for these sequences. Amino acid identities with the human sequence are shaded black and similarities are shaded grey. ‘Invariant’ amino acids of the MutT motif are shown by . The numbers to the right and left of the sequences are the amino acid positions in each complete sequence. Numbers in the right-hand column are the E-values for these sequences from a BLAST 2.0 search of the GenBank EST and non-redundant databases, with the complete YSA1H as query sequence. The E-value is a significance threshold representing the number of hits expected by chance when searching the database with the query sequence.

© 1999 Biochemical Society

The same species of apparent molecular mass 33 kDa was observed after examination of whole cell lysates prepared from human KB nasopharyngeal carcinoma cells (Figure 6a, lane 4, and Figure 6b, lane 2), human U937 promonocytic cells (Figure 6b, lane 1) and human erythrocytes (Figure 6b, lane 3). In addition, two extra bands of approx. 66 and 64 kDa were observed in the cell extracts. These might have been dimers resulting from incomplete sample denaturation; alternatively, they might have been unrelated proteins. We have previously identified two abundant proteins that cross-react strongly with another recombinant MutT motif protein, human ApA hydrolase, as hsp60 (63 kDa) and glutamate dehydrogenase (61 kDa) (J. Kyte, J. L. Cartwright and A. G. McLennan, unpublished work). The purified human erythrocyte ADP-ribose pyrophosphatase has been reported to be a dimer of 34 kDa subunits [15]. If YSA1H is the same enzyme, our results would suggest that it is in fact a dimer of 24.3 kDa subunits.

Sequence comparisons

Compilation of mouse EST data revealed a 218-residue 24 kDa mouse homologue, mYSA1H, with overall 83 % amino acid identity and 95 % similarity to the human sequence. In addition to the S. cerevisiae YSA1 gene, closely related sequences are also present in rat and Caenorhabditis elegans (Figure 7). Significant matches to sequences from the prokaryotes Treponema pallidum, Bacillus subtilis (YQKG), Synechocystis sp. and to the E. coli YRFE gene (orf186) were also obtained (Figure 7). The B. subtilis YQKG gene has been reported to encode an ADP-ribose pyrophosphatase [10]; the E. coli orf186 gene product has a broad substrate specificity including ADP-ribose, NADH and ApA [10]. The highly specific ADP-ribose pyrophosphatase from the archaeon Methanococcus jannaschii [13] and the E. coli orf209 gene product (YQIE, rdsA), which has also been reported to be an ADP-ribose pyrophosphatase [10], show only limited
similarly to YSA1H overall but do show similarities in the region surrounding the MutT motif, in addition to the invariant amino acid residues of the motif itself, which might be involved in determining substrate specificity.

DISCUSSION

One mitochondrial and three cytosolic ADP-ribose pyrophosphatases have previously been partly purified from rat liver. The cytosolic ADP-ribose I and the mitochondrial enzyme are very similar in terms of low (micromolar) $K_m$ for ADP-ribose and a stringent substrate specificity limited to ADP-ribose and IDP-ribose [16,24]. A similar activity has also been reported in embryonic cysts of the brine shrimp Artemia franciscana [25]. The cytosolic Mn$^{2+}$-dependent ADP-ribose has no activity at all with Mg$^{2+}$ [16]. Therefore YSA1H does not seem to correspond to any of these enzymes. Its marked preference for ADP-sugar substrates indicates a closer similarity to the ADP-sugar pyrophosphatase activity detected in various mammalian liver extracts, including calf and rabbit, although the range of substrates analysed with this enzyme is rather limited [17]. There are also similarities to rat liver ADP-ribose II and the human erythrocyte ADP-ribose pyrophosphatase. These enzymes have a relatively high $K_m$ for ADP-ribose (50–100 $\mu$M for rat, 170 $\mu$M for human erythrocyte and 60 $\mu$M for YSA1H) [15,16], whereas the native molecular mass of 47 kDa reported for rat ADP-ribose II [16] corresponds well to a dimer of 24.3 kDa subunits, the known subunit molecular mass of YSA1H. Apparent differences in substrate specificity include: (1) the high activity of the human erythrocyte enzyme with IDP-ribose and GDP-mannose [15]; (2) the lack of activity of the human erythrocyte enzyme with ADP-glucose [12] and (3) the high activity of the other enzymes with nicotinamide adenine dinucleotides. In the last case, significant contamination of commercial nucleotides with ADP-ribose was a likely cause of variation in results [16]. Because significant differences are apparent in the reported data for the same enzyme for human erythrocytes [12,15] and because rat ADP-ribose II exhibits a much broader specificity for NDP-sugars and nucleoside 5'-diphosphoalcohols in the presence of Mn$^{2+}$ ions [16], differences in assay procedures and conditions might have a large role in the observed differences. Taken together, these results suggest that YSA1H, the human erythrocyte ADP-ribose pyrophosphatase, rat liver ADP-ribose II and mammalian liver ADP-sugar pyrophosphatase might be the same enzyme. However, this conclusion requires confirmation.

Fluoride is a potent inhibitor of several nudix hydrolases involved in diadenosine polyphosphate metabolism [7,18,26]. Because it also inhibits YSA1H with an IC$_{50}$ of 20 $\mu$M, such inhibition might be a more general feature of this protein family. Because the specific rat liver and Artemia pyrophosphatase I enzymes are similarly inhibited by fluoride [25], it is possible that they too are nudix hydrolases related to the specific M. jannaschii enzyme. The very stringent substrate specificity of these last three enzymes suggests that activities of this type might form the first line of defence against protein glycation by free ADP-ribose. However, ADP-sugars other than ADP-ribose are not significant metabolites in mammalian cells. ADP-glucose is an important precursor for bacterial glycogen and plant starch synthesis [27], whereas ADP-mannose has no known physiological function, although the commercially available synthetica compound can replace ADP-ribose in bacterial outer-membrane lipopolysaccharide synthesis in vitro [28]. ADP-ribose might therefore also be the most important substrate for human YSA1H in vivo.

Of the other potential substrates, Ap$_3$A is the most recent of the diadenosine polyphosphates to be identified in vivo. It is present in specific granules in human myocardium and can attain an intragranular concentration of 9 mM [29]. When released extra-cellularly, it acts as a coronary vasodilator. Within the granules, however, it might not be accessible to YSA1H and so might not be a significant substrate in vivo.

In conclusion, this study describes the biochemical properties of a new human member, YSA1H, of the MutT motif family of nucleotide pyrophosphatases and suggests a possible function. However, unequivocal confirmation of this function must await the results of genetic knock-out studies in yeast, C. elegans and mouse.

We thank M. C. Wilkinson for N-terminal sequencing and M. C. Prescott for mass spectrometric analysis. This work was supported by project grant GS0308 from the Wellcome Trust and grant no. F25BJ from the Leverhulme Trust.
